Faculty : Agriculture

Manganese toxicity is one of the growth limiting factors under acidic conditions. Some plants accumulate Mn more in the top than in the root, while others accumulate more in the root than in the top. Vegetable soybean is an indicator plant that can be used to determine the mechanism of toxicity. Part of the plant tissue that accumulates the highest Mn needs to be extracted so as to determine the activity of superoxide dismutase (SOD). In view of this, a series of experiments was conducted to determine the accumulation of Mn in the tissues (leaf, stem, root and pod) of vegetable soybean, toxic level of Mn in solution culture, time-dependent of Mn accumulation in the tissue and the effect

of Mn concentration on superoxide dismutase activity under different time of plant growth.

Five experiments were conducted in glass house and laboratories at UPM. Experiment 1 was a sand culture experiment to determine the distribution of Mn accumulation in the plant tissues. Experiment 2 and 3 were solution culture experiments to observe toxic level of Mn. Experiment 4 was used to determine time-dependent of Mn accumulation, while experiment 5 was used to study the effect of Mn and time on superoxide dismutase activity.

The results showed that the highest accumulation of Mn in vegetable soybean was in the leaves. The Mn concentration corresponding to 20 % reduction in dry weight was 20 μM . Plant accumulated Mn more during vegetative stage compared to generative stage. Increasing the time of growth decreased the accumulation of Mn in the 5 and 25 μM of Mn treatments. Degeneration of plant cell in toxic condition (25 μM) affected the growth of plant and inhibited nutrient movement from the root to the shoot. Enzyme extraction showed that the activity of superoxide dismutase increased up to 25.36 $\mu\text{mol mL}^{-1}$ of crude enzyme minute^{-1} at level 15 μM after 20 days of plant age in solution culture.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia
sebagai memenuhi keperluan untuk ijazah Doktor Falsafah

**AKUMULASI MANGAN DAN KETOKSIKAN, DAN
AKTIVITI SUPEROKSIDA DISMUTASI PADA KACANG SOYA SAYURAN
(*GLYCINE MAX* (L.) MERR.)**

Oleh

ROSMAIDAR DJAFRUDDIN

September 2001

Pengerusi : Dr. Anuar Abd Rahim

Fakulti : Pertanian

Ketoksikan mangan (Mn) adalah salah satu faktor penghalang tumbesaran dalam keadaan berasid. Beberapa tanaman mengumpul Mn pada bahagian atas lebih banyak berbanding akar, sementara yang lain mengumpul pada akar lebih banyak berbanding bahagian atas. Kacang soya sayuran adalah tanaman penunjuk digunakan untuk menguji mekanisme ketoksikan Mn. Bahagian tisu yang boleh mengumpul Mn dengan banyak diperlukan untuk mengekstrak bagi menentukan aktiviti superoksida dismutasi (SOD). Berdasarkan masalah ini, beberapa kajian dijalankan untuk menguji pengumpulan Mn pada setiap bahagian tisu kacang soya sayuran (daun, batang, akar dan buah), paras toksik Mn dalam larutan nutrien, pergantungan

masa pengumpulan Mn di dalam tisu dan pengaruh kepekatan Mn terhadap aktiviti superoksida dismutasi dalam tempoh masa tumbesaran.

Lima kajian telah dijalankan di rumah kaca dan makmal UPM. Kajian 1 adalah untuk menentukan penyebaran pengumpulan Mn di dalam tisu tanaman menggunakan kultura pasir. Kajian 2 dan 3 adalah kajian di dalam larutan nutrien untuk menentukan paras toksik Mn. Kajian 4 dijalankan untuk menentukan pergantungan masa pengumpulan Mn, manakala kajian 5 untuk mengkaji pengaruh kepekatan Mn dan masa terhadap aktiviti superoksida dismutasi (SOD).

Keputusan kajian menunjukkan pengumpulan Mn tertinggi adalah pada daun kacang soya berbanding batang, akar dan buah. Paras Mn yang bersamaan dengan 20 % penurunan berat kering adalah 20 μM . Kacang soya sayuran mengumpul Mn lebih tinggi pada masa vegetatif berbanding reproduktif. Penambahan masa tumbesaran mengurangkan pengumpulan Mn pada 5 dan 25 μM Mn. Kemerosotan pertumbuhan sel pada tanaman dalam keadaan toksik Mn (25 μM) telah mempengaruhi tumbesaran tanaman dan mengganggu pergerakan nutrien dari akar ke pucuk. Pengekstratan enzim menunjukkan bahawa aktiviti superoksida dismutasi meningkat sehingga 25.36 $\mu\text{mol mL}^{-1}$ enzim mentah minit^{-1} pada 15 μM selepas 20 hari di dalam larutan nutrien.

ACKNOWLEDGEMENTS

I wish to express my sincere appreciation to Dr. Anuar Abd Rahim, Chairman of my Supervisory committee, for his guidance and encouragement throughout the thesis research. Special thanks are also extended to the other members of the committee, Professor Dr. Shamshuddin Jusop and Professor Dr. Hasanah M. Ghazali, for their assistance in the preparation of this manuscript.

Thanks are also due to my international graduate friends, lab technicians in the Faculty of Agriculture. Special thanks to my colleagues Mohd Yusof Mohd Nor, Lokman Mohd Zein (Jabatan Persuratan Melayu UKM Bangi) and Professor Mohd N Farooqui (Department of Electronics and Electrical Communication Engineering IIT Kharagpur, India) for their support throughout my educational career.

I am deeply indebted to the MTCP (Malaysian Technical Cooperation Program) for awarding me a scholarship during my study leave and Universitas Syiah Kuala, Banda Aceh, Indonesia for the extension of my study-leave.

Finally, deepest thanks to my father Djafruddin (Alm), my mother Nuraini (Almh), my son Romiandi Mohd Rizal, my sisters; Mardiani Djafruddin, Linda Djafruddin, Hernita Djafruddin, Yurlida Djafruddin, Fitrianti Djafruddin and my brothers; Safri Djafruddin, M. Jumadi Djafruddin, for their sacrifices, understanding and support they have given me throughout my educational pursuit.

I certify that an Examination Committee met on 24th September 2001 to conduct the final examination of Rosmaidar Djafruddin on her Doctor of Philosophy thesis entitled "Manganese Accumulation and Toxicity, and Superoxide Dismutase Activity in Vegetable Soybean (*Glycine max* (L.) Merr.)" in accordance with Universiti Pertanian Malaysia (Higher degree) Act 1980 and Universiti Pertanian Malaysia (Higher degree) Regulation 1981. The Committee recommends that the candidate be awarded the relevant degree. Members of the Examination Committee are as follows:

Zaharah A. Rahman, Ph.D.
Professor,
Department of Land Management,
Faculty of Agriculture,
Universiti Putra Malaysia,
(Chairman)

Anuar Abd Rahim, Ph.D.
Department of Land Management,
Faculty of Agriculture,
Universiti Putra Malaysia,
(Main supervisory)

Shamshuddin Jusop, Ph.D.
Professor,
Department of Land Management,

CHAPTER ONE

INTRODUCTION

Soybean (*Glycine max* (L.) Merr.) is one of the important crops that has a very significant, diverse and the variety that can be used is wide range, in different food items. The United States (US) competes with China in the production of soybean for the purposes of manufacturing various soyfoods. In China soybean is used as vegetable, an important part of daily diet (Plucknett and Halsey, 1981), while in US soybean is famous as vegetable legume an important species as food source for human and animal (Vincent, 1997).

Special varieties of soybeans can be used as 'vegetable' if they are picked at the right stage. Vegetable soybean contains about 16 % protein and is rich in minerals, especially Ca, and vitamins A and B (Mookherji and Floyd, 1991). Vegetable soybean is very famous in Japan as table food. Hence, production of healthy soybean crop becomes very important all around the world. Soybean and other similar crops like potato, beetroot and others are adversely affected by the presence of naturally occurring Mn absorbed directly from the soil.
